SPI Driver for Enhanced Relay Control TLE7235EM

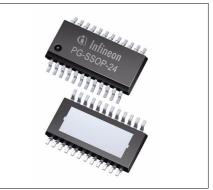

TLE7235EM

1 Overview

Features

- 8 bit SPI for diagnostics and control, providing daisy chain capability
- Very wide range for digital supply voltage
- Two configurable input pins offer complete flexibility for PWM operation
- Stable behavior at under voltage
- Green Product (RoHS compliant)
- AEC Qualified

PG-SSOP-24-4

Description

The TLE7235EM is an eight channel high-side and low-side power switch in PG-SSOP-24-4 package providing embedded protective functions. It is especially designed for standard relays and LEDs in automotive applications.

The output stages incorporate two low-side, four high-side and two auto configuring high-side or low-side switches.

A serial peripheral interface (SPI) is utilized for control and diagnosis of the device and the load. For direct control, there are two input pins available.

The TLE7235EM provides a micro controller fail-safe function which is activated via a high signal at the limp home input pin. There is a power supply integrated in the device to ensure this functionality even without digital supply voltage.

The power transistors are built by N-channel power MOSFETs. The device is monolithically integrated in Smart Power Technology.

Overview

Table 1Product Summary

Operating range power supply voltage	$V_{\rm bb}$	5.5 28 V
Digital supply voltage	V _{DD}	3.0 5.5 V
Typical On-State resistance at 25 °C	R _{DS(ON)}	
high-side: 2 channels (Relay)		0.9 Ω
high-side: 2 channels (Generic, LED)		1.6 Ω
auto configuring: 2 channels (Relay, Supplies)		0.9 Ω
low-side: 2 channels (Relay)		0.9 Ω
Nominal load current (all channels active)	I _{L(nom, min)}	
Relay		350 mA
LED, Generic		175 mA
Over load switch off threshold	I _{DS(OVL, min)}	500 mA
Output leakage current per channel at 25 °C	I _{DS(OFF, max)}	1 μA
Drain to source clamping voltage	V _{DS(CL, min)}	41 V
Source to ground clamping voltage	$V_{\rm bb(CL,\ max)}$	-40 V
SPI clock frequency	f _{SCLK(max)}	5 MHz

Protective Functions

- · Over load and short circuit protection
- Thermal shutdown
- Electrostatic discharge protection (ESD)

Diagnostic Functions

- Latched diagnostic information via SPI
- · Open load detection in OFF-state
- Over load detection in ON-state
- Over temperature

Limp Home / Fail-Safe Functions

- Limp home activation via pin LHI
- · Limp home configuration via input pins

Applications

- Especially designed for driving relays and LEDs in automotive applications
- All types of resistive and inductive loads
- Suitable to switch 5 V power supply lines by auto configuring channels

Overview

Detailed Description

The TLE7235EM is an eight channel high-side and low-side relay switch providing embedded protective functions. The output stages incorporate two low-side switches (0.9Ω per channel), four high-side switches (two channels with 0.9Ω and two channels with 1.6Ω) and two auto-configuring high-side or low-side switches (0.9Ω per channel). The auto-configuring switches can be utilized in high-side or low-side configuration just by connecting the load accordingly. They are also suitable to switch a 5 V supply line in high-side configuration. Protective and diagnostic functions adjust automatically to the chosen configuration.

The 8 bit serial peripheral interface (SPI) is utilized for control and diagnosis of the device and the loads. The SPI interface provides daisy chain capability in order to assemble multiple devices in one SPI chain by using the same number of micro-controller pins.

Furthermore, the TLE7235EM is equipped with two input pins that can be individually routed to the output control of each channel thus offering complete flexibility in design and PCB-layout. The input multiplexer is controlled via SPI.

In limp home mode (fail-safe mode), the input pins are directly routed to the configurable output channels 4 and 5. The limp home mode operates independently of digital power supply and is activated via pin LHI.

The device provides full diagnosis of the load via open load, over load and short circuit detection. SPI diagnosis flags indicate latched fault conditions that may have occurred.

Each output stage is protected against short circuit. In case of over load, the affected channel switches off. There are temperature sensors available for each channel to protect the device against over temperature.

The device protects itself with a built in reverse polarity protection which prohibits intrinsic current flow through the logic during reverse polarity. However the output stages still incorporate a reverse diode where current can flow through during reverse polarity.

The power transistors are built by N-channel power MOSFETs. The inputs are ground referenced CMOS compatible. The device is monolithically integrated in Smart Power Technology.

2.1 Terms

Figure 2 shows all terms used in this data sheet.

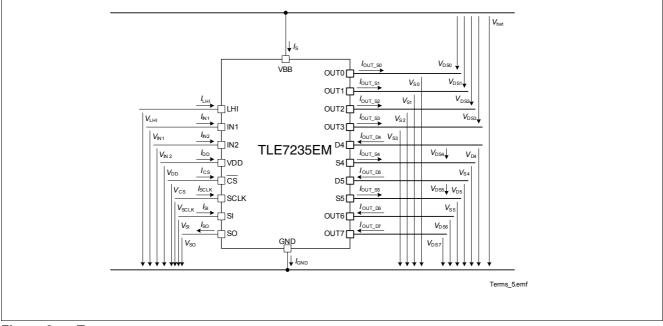

Figure 2 Terms

In all tables of the electrical characteristics is valid:

Channel related symbols without channel number are valid for each channel separately (e.g. V_{DS} specification is valid for $V_{\text{DS0}} \dots V_{\text{DS7}}$). In order to make the description of output currents easier, the load current I_{Out} is equivalent to the drain current I_{OUT} in low-side configuration and the source current I_{OUT} in high-side configuration. All SPI register bits are marked as follows: ADDR.PARAMETER (e.g. ICR01.INX1). In SPI register description,

the values in bold letters (e.g. **0**) are default values.

1) Not subject to production test

2) Specified R_{thJSP} value is simulated at natural convection on a cold plate setup (all pins are fixed to ambient temperature). $T_{a} = 85 \text{ °C}$. Ch1 to Ch8 are dissipating 1 W power (0.125 W each).

3) Specified R_{thJA} value is according to Jedec JESD51-2,-3 at natural convection on FR4 1s0p board; The product (Chip+Package) was simulated on a 76.2 x 114.3 x 1.5 mm board with minimal footprint copper area and 70 μ m thickness. T_a = 85 °C, Ch1 to Ch8 are dissipating 1 W power (0.125 W each).

4) Specified R_{thJA} value is according to Jedec JESD51-2,-3 at natural convection on FR4 1s0p board; The product (Chip+Package) was simulated on a 76.2 x 114.3 x 1.5 mm board with additional heatspreading copper area of 300mm² and 70 μ m thickness. T_a = 85 °C, Ch1 to Ch8 are dissipating 1 W power (0.125 W each).

5) Specified R_{thJA} value is according to Jedec JESD51-2,-3 at natural convection on FR4 1s0p board; The product (Chip+Package) was simulated on a 76.2 x 114.3 x 1.5 mm board with additional heatspreading copper area of 600mm² and 70 μ m thickness. T_a = 85 °C, Ch1 to Ch8 are dissipating 1 W power (0.125 W each).

6) Specified R_{thJA} value is according to Jedec JESD51-2,-7 at natural convection on FR4 2s2p board; The product (Chip+Package) was simulated on a 76.2 x 114.3 x 1.5 mm board with 2 inner copper layers (2 x 70 μm Cu, 2 x 35 μm Cu). T_a = 85 °C, Ch1 to Ch8 are dissipating 1 W power (0.125 W each).

Power Supply

5 **Power Supply**

The TLE7235EM is supplied by two supply voltages V_{bb} and V_{DD} . The V_{bb} supply line is connected to a battery feed and used by the power switches and by an integrated power supply for the register banks. There is an under voltage reset function implemented for the V_{bb} power supply, which is triggered if V_{bb} is below the undervoltage threshold. After start-up of the power supply, all SPI registers are reset to their default values and the device is in sleep mode (standby). Sending the SPI command CMD.WAKE = 1 switches the device to operation mode (ON), while a command CMD.STB = 1 send the device to sleep mode (standby) again. Please note that the device needs the time $t_{wu(Sleep)}$ to initialize itself. No SPI command should be send after changing the power state via CMD.WAKE = 1 before this time is elapsed. A SPI frame send during $t_{wu(Sleep)}$ could be ignored.

The $V_{\rm DD}$ supply line is used to power the circuitry related to the SPI shift register and for driving the SO line. As a result, the daisy chain function is available as soon as $V_{\rm DD}$ is provided in the specified range independent of $V_{\rm bb}$.

A capacitor between pins V_{DD} and GND is recommended (especially in case of EMI disturbances).

Please see Figure 14 "Application Diagram" on Page 35 for details.

5.1 Operation Modes

There is a limp home functionality implemented in the TLE7235EM, which is activated via pin LHI. Please refer to **Section 5.2** for details.

The device provides a sleep mode (stand by) to minimize current consumption, which also resets the register banks. It is entered and left by dedicated SPI commands . The sleep mode current is minimized only when limp home is inactive. After limp home, the device enters sleep mode automatically.

The following table shows the operation modes depending on V_{bb} , V_{DD} and the limp home input signal LHI.

Operation Modes							
VBB	0 V	0 V	0 V	12 V	12 V	12 V	12 V
VDD	0 V	5 V	5 V	0 V	0 V	5 V	5 V
LHI	Х	0 V	5 V	0 V	5 V	0 V	5 V
Switches operating	-	-	-	1	1	1	1
Limp Home	-	-	-	-	1	-	1
SPI & daisy-chain	-	1	1	-	-	1	1
Register Banks	reset	reset	reset	1	reset	1	reset
Diagnostic functions	-	-	-	1	-	1	-

5.2 Limp Home Mode

The TLE7235EM offers the capability of driving dedicated channels during fail-safe operation of the system. This limp home mode is activated by a high signal at pin LHI. In limp home mode, the SPI registers are reset and the input pins are directly routed to the auto configuring channels (channel 4 and 5). As a result, the limp home operation can be chosen for high-side and low-side driven loads. Due to the integrated power supply, limp home operation is independent of digital power supply $V_{\rm DD}$. In case of stand-by, a high signal at pin LHI will wake up the device. After limp home operation, the device enters sleep mode in any case.

5.3 Reset

There are several reset trigger implemented in the device. A reset switches off all channels and sets the registers to default values. After any kind of reset, the transmission error flag (TER) is set and the device is in sleep mode.

Under Voltage Reset:

Power Supply

During this device condition a read on SPI delivers the Standard Diagnostic Frame with a TER flag, if V_{DD} is above the under voltage threshold already, if not SPI is not working.

This under voltage reset is released when V_{DD} and V_{bb} supply voltage levels are above under voltage threshold.

Reset Command: There is a reset command available to reset all register bits of the register bank and the diagnosis registers. As soon as CMD.RST = 1, a reset is triggered.

Limp Home Mode: In limp home mode, the SPI write-registers are reset. The SPI interface is operating normally, so the limp home bit LHI as well as the diagnosis flags can be read, but no command is accepted until the device leaves the Limp home operation.

Power Supply

5.4 Electrical Characteristics

Unless otherwise specified:

 $V_{\rm DD}$ = 3.0 V to 5.5V, $V_{\rm BAT}$ = 9.0 V to 16V, $T_{\rm i}$ = -40 °C to +150 °C

1) Not subject to production test, specified by design.

Note: Characteristics show the deviation of parameter at the given supply voltage and junction temperature. Typical values show the typical parameters expected at V_{bb} = 13.5 V, V_{DD} = 5.0 V, T_j = 25 °C.

6 Power Stages

The TLE7235EM is an eight channel high-side and low-side relay switch. The power stages are built by N-channel vertical power MOSFET transistors. The gates of the high-side switches are controlled by charge pumps.

6.1 Input Circuit

There are two input pins available at TLE7235EM, which can be configured to be used for control of the output stages. The INXn parameter of the input configuration register provide following possibilities:

- channel is switched off
- channel is switched according to signal level at input pin IN1
- channel is switched according to signal level at input pin IN2
- channel is switched on

Figure 4 shows the input circuit of TLE7235EM.

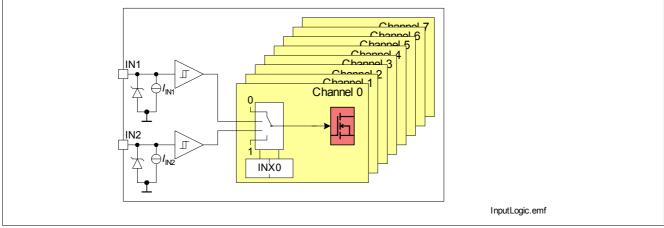

Figure 4 Input Multiplexer

The current sink to ground ensures that the channels switch off in case of open input pin. The zener diode protects the input circuit against ESD pulses.

6.2 Channels 4 and 5

The TLE7235EM provides two auto-configuring high-side or low-side switches (channels 4 and 5). They adjust the diagnostic and protective functions according their potentials at drain and source automatically.

In high-side configuration, the load is connected between ground and source of the power transistors (S4 or S5). The drain of the power transistors (D4 and D5) can be connected to any potential between GND-pin potential and VBB-pin potential. When the drain is connected to VBB, the channel behave like the other high side channels. The drain can also be connected to a 5 V power supply and the source pin will be utilized as switched 5 V supply line.

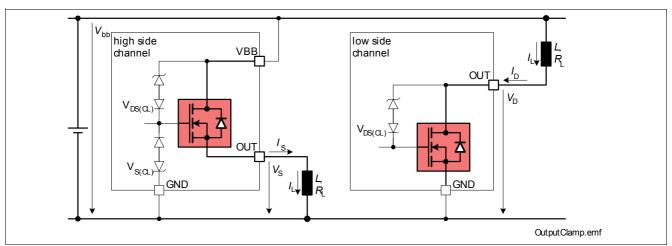

In low-side configuration, the source of the power transistors are to be connected to GND.

The configuration can be chosen for each of these channels individually, so it is feasible to connect one channel in low-side and the other in high-side configuration.

6.3 Inductive Output Clamp

When switching off inductive loads with low-side switches, the potential at pin OUT rises to $V_{\text{DS(CL)}}$ potential, because the inductance intends to continue driving the current. For the high-side channels, the potential at pin OUT drops below ground potential to $V_{\text{S(CL)}}$. The voltage clamping is necessary to prevent destruction of the device, see **Figure 5** for details. Nevertheless, the maximum allowed load inductance is limited by the max. clamping energy E_{AR} see electrical characteristics " E_{AR} " on Page 10.

Maximum Load Inductance

During demagnetization of inductive loads, energy has to be dissipated in the TLE7235EM. This energy can be calculated with following equations:

$$E = V_{\text{DS(CL)}} \cdot \left[\frac{V_{\text{bb}} - V_{\text{DS(CL)}}}{R_{\text{L}}} \cdot \ln \left(1 - \frac{R_{\text{L}} \cdot I_{\text{L}}}{V_{\text{bb}} - V_{\text{DS(CL)}}} \right) + I_{\text{L}} \right] \cdot \frac{L}{R_{\text{L}}} \quad \text{Low-side}$$
(1)

$$E = (V_{bb} - V_{S(CL)}) \cdot \left[\frac{V_{S(CL)}}{R_L} \cdot \ln\left(1 - \frac{R_L \cdot I_L}{V_{S(CL)}}\right) + I_L\right] \cdot \frac{L}{R_L}$$
 High-side (2)

These equations simplify under the assumption of $R_{\rm L}$ = 0:

$$E = \frac{1}{2}LI_{L}^{2} \cdot \left(1 - \frac{V_{bb}}{V_{bb} - V_{DS(CL)}}\right)$$
 Low-side (3)

$$E = \frac{1}{2}LI_{\rm L}^2 \cdot \left(1 - \frac{V_{\rm bb}}{V_{\rm S(CL)}}\right)$$
 High-side (4)

The maximum energy, which is converted into heat, is limited by the thermal design of the component.

6.4 Timing Diagrams

The power transistors are switched on and off with a dedicated slope via the INX bits of the serial peripheral interface (SPI). The switching times t_{ON} and t_{OFF} are designed equally.

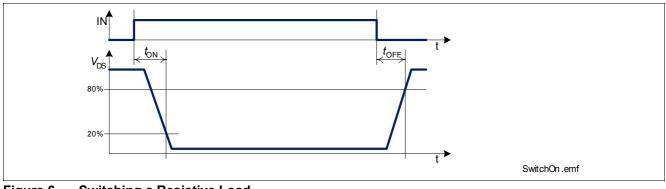

Figure 6 Switching a Resistive Load

In input mode, a high signal at the input pin is equivalent to a SPI ON command and a low signal to SPI OFF command respectively. Please refer to **Section 9.3** for details on SPI protocol.

6.5 Electrical Characteristics

Protection Functions

7 Protection Functions

The device provides embedded protective functions. Integrated protection functions are designed to prevent IC destruction under fault conditions described in this data sheet. Fault conditions are considered as "outside" normal operating range. Protection functions are not designed for continuous repetitive operation.

7.1 Over Load Protection

The TLE7235EM is protected in case of over load or short circuit of the load. After time $t_{OFF(OVL)}$, the over loaded channel n switches off and the according diagnosis flag Dn is set. The channel can be switched on after clearing the protection latch by command CMD.CPL = 1. The CPL command clears itself with the next valid SPI communication frame. Please refer to Figure 7 for details.

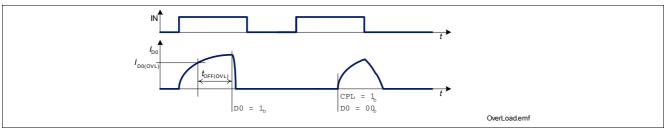

Figure 7 Shut Down at Over Load

7.2 Over Temperature Protection

A temperature sensor for each channel causes an overheated channel to switch off to prevent destruction. The according diagnosis flag is set. This flag is also set in OFF state, if the regarding channel temperature is too high. The channel can be only switched on after clearing the protection latch by SPI command CMD. CPL = 1. The CPL command clears itself with the next valid SPI communication frame. Please refer to "Diagnostic Features" on Page 23 for information on diagnosis features.

7.3 ESD protection

There is a designed in protection against ESD disturbances up to the specified limit by using the defined model. Please see electrical characteristics **"ESD susceptibility on all pins" on Page 11**

7.4 Reverse Polarity Protection

There is a reverse polarity protection implemented in the TLE7235EM. This protection has to be divided into two parts. First the protection of the control circuits and second in the protection of the power transistors.

The control circuits are reverse polarity protected by protective measures in the ground connection. In case of reverse polarity, there is no current flow through the control circuits. To ensure this functionality, the GND pin and the substrate connections SUB must not be connected to the same potential. This means, the copper area dedicated for cooling should be connected at SUB and needs to be electrically isolated from GND.

The power transistors contain intrinsic body diodes that cause power dissipation. The reverse current through these intrinsic body diodes has to be limited by the connected loads. The over temperature and over load protection are not active during reverse polarity.

7.5 Loss of $V_{\rm bb}$

In case of loss of V_{bb} connection in on-state, all inductances of the loads have to be demagnetized through the an additional path from V_{bb} to ground. Usually this path is given somewhere in the PCB circuitry, for example, as a suppressor diode like in the application diagram (see D1 in Figure 14 "Application Diagram" on Page 35).

Protection Functions

Electrical Characteristics 7.6

Unless otherwise specified:

 $V_{\rm DD}$ = 3.0 V to 5.5V, $V_{\rm BAT}$ = 9.0 V to 16V, $T_{\rm j}$ = -40 °C to +150 °C typical values: $V_{\rm DD}$ = 5.0 V, $V_{\rm BAT}$ = 13.5 V, $T_{\rm j}$ = 25 °C

8 Diagnostic Features

The SPI of TLE7235EM provides diagnosis information about the device and about the load. The diagnosis information of the protective functions of channel n is latched in the diagnosis flags Dn. It is cleared by the SPI command CMD.CPL = 1. The CPL command clears itself with the next valid SPI communication frame. The open load diagnosis of channel n is latched in the diagnosis flag OLn. This flag is cleared by reading the according diagnosis register.

Following table shows possible failure modes and the according protective and diagnostic action.

Failure Mode	Comment
Open Load	Diagnosis, when channel n is switched on: none Diagnosis, when channel n is switched off: according to voltage level at the output pin, flag OLn is set after time $t_{d(OL)}$. A diagnosis current can be enabled by SPI command DCCR.DCENn = 1.
Over Temperature	When over temperature occurs, the according diagnosis flag Dn is set. If the affected channel n was active it is switched off. The diagnosis flags are latched until they have been cleared by SPI command CMD.CPL = 1.
Over Load (Short Circuit)	When over load is detected at channel n, the affected channel is switched off after time $t_{OFF(OVL)}$ and the dedicated diagnosis flag Dn is set. The diagnosis flags are latched until they have been cleared by SPI command CMD.CPL = 1.

Diagnosis Current Configuration Register

9 Serial Peripheral Interface (SPI)

The diagnosis and control interface is based on a serial peripheral interface (SPI).

The SPI is a full duplex synchronous serial slave interface, which uses four lines: SO, SI, SCLK and \overline{CS} . Data is transferred by the lines SI and SO at the data rate given by SCLK. The falling edge of \overline{CS} indicates the beginning of a data access. Data is sampled in on line SI at the falling edge of SCLK and shifted out on line SO at the rising edge of SCLK. Each access must be terminated by a rising edge of \overline{CS} . A modulo 8 counter ensures that data is taken only, when a multiple of 8 bit has been transferred. The interface provides daisy chain capability.

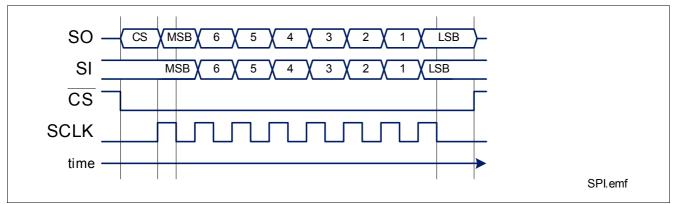

Figure 8 Serial Peripheral Interface

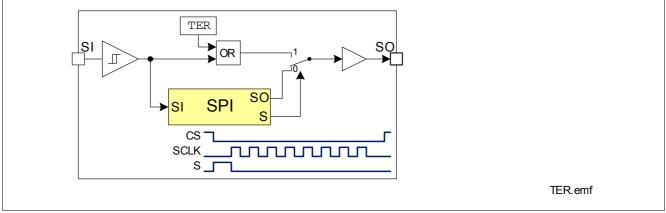

The SPI protocol is described in **Section 9.3**. It is reset to the default values after reset.

9.1 SPI Signal Description

 \overline{CS} - Chip Select: The system micro controller selects the TLE7235EM by means of the \overline{CS} pin. Whenever the pin is in low state, data transfer can take place. When \overline{CS} is in high state, any signals at the SCLK and SI pins are ignored and SO is forced into a high impedance state.

CS High to Low transition: —

- The diagnosis information is transferred into the shift register.
- SO changes from high impedance state to high or low state depending on the logic OR combination between the transmission error flag (TER) and the signal level at pin SI. As a result, even in daisy chain configuration, a high signal indicates a faulty transmission. For details, please refer to **Figure 9**. This information stays available to the first rising edge of SCLK.

CS Low to High transition:

- Command decoding is only done, when after the falling edge of CS exactly a multiple (1, 2, 3, ...) of eight SCLK signals have been detected. In case of faulty transmission, the transmission error flag (TER) is set and the command is ignored.
- Data from shift register is transferred into the input matrix register.

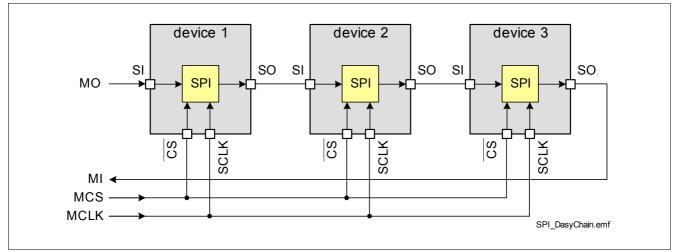

SCLK - **Serial Clock:** This input pin clocks the internal shift register. The serial input (SI) transfers data into the shift register on the falling edge of SCLK while the serial output (SO) shifts diagnostic information out on the rising edge of the serial clock. It is essential that the SCLK pin is in low state whenever chip select \overline{CS} makes any transition.

SI - Serial Input: Serial input data bits are shifted in at this pin, the most significant bit first. SI information is read on the falling edge of SCLK. The 8 bit input data consist of two parts (control and data). Please refer to **Section 9.3** for further information.

SO Serial Output: Data is shifted out serially at this pin, the most significant bit first. SO is in high impedance state until the \overline{CS} pin goes to low state. New data will appear at the SO pin following the rising edge of SCLK. Please refer to **Section 9.3** for further information.

9.2 Daisy Chain Capability

The SPI of TLE7235EM provides daisy chain capability. In this configuration several devices are activated by the same \overline{CS} signal \overline{MCS} . The SI line of one device is connected with the SO line of another device (see Figure 10), which builds a chain. The ends of the chain are connected with the output and input of the master device, MO and MI respectively. The master device provides the master clock MCLK, which is connected to the SCLK line of each device in the chain.

In the SPI block of each device, there is one shift register where one bit from SI line is shifted in each SCLK. The bit shifted out can be seen at SO. After 8 SCLK cycles, the data transfer for one device has been finished. In single chip configuration, the \overline{CS} line must go high to make the device accept the transferred data. In daisy chain configuration the data shifted out at device #1 has been shifted in to device #2. When using three devices in daisy chain, three times 8 bits have to be shifted through the devices. After that, the \overline{MCS} line must go high (see Figure 11).

Figure 11 Data Transfer in Daisy Chain Configuration

9.3 SPI Protocol

The control and diagnosis function of the TLE7235EM is based on two register banks which are accessed via following SPI protocol. The control register bank contains eight registers (with 4 bit each) addressed by a 3 bit pointer. The diagnosis register bank contains four registers (with 4 bit each) addressed by a 2 bit pointer. An additional indication bit is available to differentiate between standard diagnosis information and data read from a register bank.

Control and Diagnosis Mode

Package Outlines

10 Package Outlines

Green Product (RoHS compliant)

To meet the world-wide customer requirements for environmentally friendly products and to be compliant with government regulations the device is available as a green product. Green products are RoHS-Compliant (i.e Pb-free finish on leads and suitable for Pb-free soldering according to IPC/JEDEC J-STD-020).

For further information on alternative packages, please visit our website: http://www.infineon.com/packages.

Dimensions in mm

Application Information

11 Application Information

Note: The following information is given as a hint for the implementation of the device only and shall not be regarded as a description or warranty of a certain functionality, condition or quality of the device.

Figure 14 shows a simplified application circuit. Vdd need to be externally reverse polarity protected.

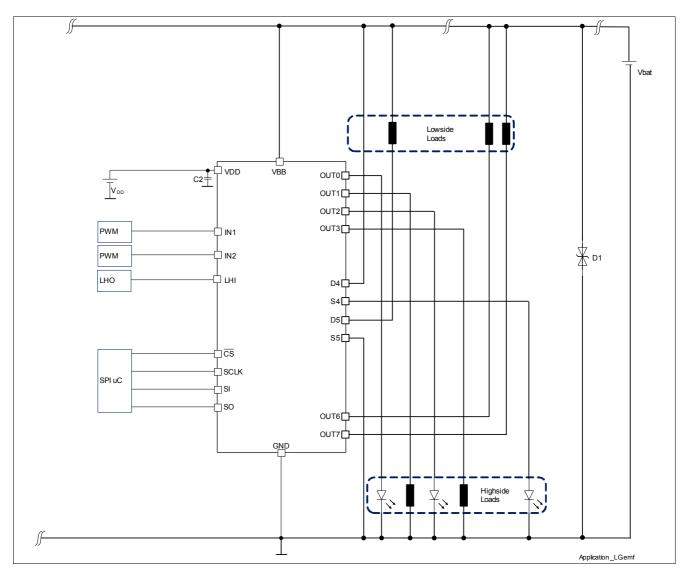

Figure 14 Application Diagram

Note: This is a very simplified example of an application circuit. The function must be verified in the real application.

The circuit above shows a example of using this device in a automotive target application.

D1 is optional for loss of battery or loss of ground if no other circuit on this battery feed can limit the voltage to the max. rating of the device (-40 V) .

C2 is for EMC and to stabilize the digital driver, recommended value is 47nF.

There are no resistors to the μ C needed due to the internal reverse polarity protection.

Legal Disclaimer

The information given in this document shall in no event be regarded as a guarantee of conditions or characteristics. With respect to any examples or hints given herein, any typical values stated herein and/or any information regarding the application of the device, Infineon Technologies hereby disclaims any and all warranties and liabilities of any kind, including without limitation, warranties of non-infringement of intellectual property rights of any third party.

Information

For further information on technology, delivery terms and conditions and prices, please contact the nearest Infineon Technologies Office (www.infineon.com).

Warnings

Due to technical requirements, components may contain dangerous substances. For information on the types in question, please contact the nearest Infineon Technologies Office.

Infineon Technologies components may be used in life-support devices or systems only with the express written approval of Infineon Technologies, if a failure of such components can reasonably be expected to cause the failure of that life-support device or system or to affect the safety or effectiveness of that device or system. Life support devices or systems are intended to be implanted in the human body or to support and/or maintain and sustain and/or protect human life. If they fail, it is reasonable to assume that the health of the user or other persons may be endangered.
