SX1230 - Integrated Transmitter IC

Narrow/wideband 315 MHz, 434 MHz 868 MHz and 915 MHz band Transmitter

GENERAL DESCRIPTION

The SX1230 is a fully integrated transmitter which can operate in the 315, 434, 868 and 915 MHz licence free ISM bands.

The transmitter has two modes of operation, a conventional MCU controlled mode and a 'stand-alone' mode which enables the SX1230 to download configuration and messages from an E^2 PROM in response to a user input.

Stand-alone mode makes the SX1230 ideal for miniaturized or low cost remote keyless entry (RKE) applications. It also offers the unique advantage of narrow-band and wide-band communication in a range of modulation formats.

The SX1230 offers high RF output power and channelized operation suited for the European (ETSI EN 300-220-1), North American (FCC part 15.231, 15.247 and 15.249) and Japanese (ARIB T-67) regulatory standards.

ORDERING INFORMATION

APPLICATIONS

- ◆ Remote Keyless Entry (RKE)
- Remote Control / Security Systems
- Voice and Data RF Communication Links
- **•** Process and building / home control
- ◆ Active RFID
- AMR / AMI Platforms

KEY PRODUCT FEATURES

- +17 dBm to -18 dBm Programmable output power.
- ◆ Bit rates up to 300 kbits / sec.
- FSK, GFSK, MSK, GMSK and OOK modulation.
- Stand-alone mode: No need for a host MCU.
- Consistent RF performance over a 1.8 to 3.7 V range.
- Low phase noise (-95 dBc/Hz at 50 kHz) with automated PLL calibration and fully integrated VCO and loop filter.
- On chip RC timer for timer / wake-up applications.
- Low battery detection.

SX1230

This product datasheet contains a detailed description of the SX1230 performance and functionality. Please consult the Semtech website for the latest updates or errata (www.semtech.com).

1. General Description

The SX1230 is a multi-band, single chip transmitter IC capable of (G)FSK, (G)MSK, and OOK modulation of an input data stream. It can transmit this modulated signal in any of the license free ISM bands from 290 MHz to 1020 MHz.

1.1. Simplified Block Diagram

Figure 1. SX1230 Simplified Block Diagram

The general architecture of the SX1230 is shown in [Figure 1.](#page-3-2) The frequency synthesizer generating the LO frequency is a third-order fractional-N sigma-delta PLL. The PLL is capable of fast auto-calibration and offers fast switching and settling times. For frequency modulation ((G)FSK and (G)MSK), the modulation is performed within the PLL bandwidth. Optional pre-filtering of the bit stream may also be enabled to reduce the power delivered to adjacent channels.

Amplitude modulation (OOK), is performed via a DAC driving the reference of the regulator of the PA. Note that pre-filtering of the bit stream is also available in this mode. The VCO works at 2, 4 or 6 times the RF output frequency to improve the quadrature precision and reduce pulling effects during transmission.

The PA of the SX1230 is comprised of two amplifiers - one high power, one low power. This enables the SX1230 to deliver a wide range, over 30 dB, of output powers - up to +13 dBm in single PA configuration. However, with an appropriate output impedance transformation, in dual PA mode, this can be increased to +17 dBm.

ADVANCED COMMUNICATIONS & SENSING PRELIMINARY DATASHEET

The SX1230 also includes two timing references; an RC oscillator, for sleep mode operation of the SPI interface (in MCU mode), and a 32 MHz crystal oscillator, which serves as the low-noise frequency reference of the PLL. The references and supply voltages are provided by the power distribution system which includes several regulators allowing true battery powered operation.

1.2. Pin Diagram

The following diagram shows the pinouts of the 4x4 mm MLPQ-24 package.

Table 1 Description of the SX1230 Pinouts

ADVANCED COMMUNICATIONS & SENSING PRELIMINARY DATASHEET

SX1230

2. Electrical Characteristics

2.1. ESD Notice

The SX1230 is an electrostatic discharge sensitive device. It satisfies:

- Class 1C of the JEDEC standard JESD22-A114-B (human body model) on pins 2, 10, 21 and 23.
- Class 2 of the JEDEC standard JESD22-A114-B (human body model) on all other pins.

2.2. Absolute Maximum Ratings

Stresses above the values listed below may cause permanent device failure. Exposure to absolute maximum ratings for extended periods may affect device reliability.

Table 2 Absolute Maximum Ratings

2.3. Operating Range

Operating ranges define the limits for functional operation and the parametric characteristics of the device as described in this section. Functionality outside these limits is not implied.

Table 3 Operating Range

Symbol	Description	Min	Max	Unit
VDDop	Supply voltage	1.8	3.7	ν
Top	Operational temperature range	-40	85	$^{\circ}$ C
Clop	Load capacitance on digital ports	-	25	pF

ADVANCED COMMUNICATIONS & SENSING PRELIMINARY DATASHEET

2.4. Electrical Specifications

The table below gives the electrical specifications of the transmitter under the following conditions: Supply voltage = 3.3 V, temperature = 25 °C, f_{XOSC} = 32 MHz, f_{RF} = 915 MHz, 2-level FSK modulation without prefiltering, Δf = 5 kHz, bit rate = 4.8 kbit/s and output power = 13 dBm terminated in a matched 50 ohm impedance, unless otherwise specified.

Table 4 Transmitter Specifications

ADVANCED COMMUNICATIONS & SENSING PRELIMINARY DATASHEET

3. Timing Characteristics

The following table gives the operating specifications for the SPI interface of the SX1230. *Table 5 SPI Timing Specifications*

For explanatory diagrams of the timing characteristic parameters, please see [Figure 7](#page-18-0) and [Figure 8](#page-18-1).

ADVANCED COMMUNICATIONS & SENSING PRELIMINARY DATASHEET

4. Working Modes of the SX1230

4.1. Operating Modes

The four operating modes of the SX1230 are shown in [Table 6.](#page-9-4) Each of these may be selected via the SPI bus by writing the corresponding bits to Mode(2:0). A key feature of the SX1230 is that the transition from one operating mode to the next is automatically optimized. For example, if the transmit operating mode is selected whilst in sleep operating mode then, in a pre-defined time-optimized sequence, each of the intermediate modes is engaged sequentially without the need to issue any further SPI commands. For more information on timing and optimization please see Section [7.4](#page-28-0).

4.2. Application Modes

The SX1230 has two application modes, selected by applying an external logical level to the E2_MODE input (pin 6). The first, MCU mode (E2_Mode= '0'), configures the SX1230 as an SPI slave. This permits the configuration of the circuit by an external microprocessor via the SPI interface of the SX1230 and the data to be applied via the DATA input (pin 14). The second application mode, stand-alone mode (E2_Mode = 0), sees the SX1230 configured as SPI master. In the standalone application mode the SX1230 can download its configuration from an external SPI E²PROM. Moreover, in response to an input on the GPIO pins, a specific configuration can be programmed and a payload transmitted.

Note that this mode selection process is performed at start up (or POR) of the circuit. Thus the hardware mode cannot be dynamically changed without resetting the chip. This may be achieved either by power down or by issuing an active high POR signal to the Reset input (pin 5).

4.2.1. Stand Alone Mode

In stand alone mode (E2 Mode = '1') the SX1230 will operate as a stand-alone SPI master which can download both register settings and data payload from an SPI E^2 PROM. Four debounced GPIO inputs are available in stand alone mode, in this application mode the SX1230 remains in sleep operating mode until either a single or combination of button presses are detected. SX1230 can then be dynamically reconfigured and / or transmit a data sequence stored within the E^2 PROM.

The SX1230 can accommodate SPI E²PROM sizes up to 8 kbit and uses industry standard SPI commands. For a full description of E^2 PROM use with SX1230 and the associated application circuits, please see Section [6.1.](#page-14-1) The application circuit for stand-alone operation is shown in [Figure 3,](#page-10-1) note that both matching and L_M are band specific whilst C_{TX} is application specific.

SX1230

Integrated Transmitter IC

ADVANCED COMMUNICATIONS & SENSING PRELIMINARY DATASHEET

Figure 3. SX1230 Stand-Alone Application Circuit

4.2.2. MCU Mode

The SX1230 is also capable of operating in a conventional MCU controlled mode. [Figure 4](#page-10-2) shows the SX1230 operating in MCU mode and connected to an external microcontroller. Note that CLKOUT provides the oscillator signal for the MCU, thus negating the need for two crystal oscillators. The DCLK connection is also optional - only being required if the data rate is to be determined by SX1230 or transmit filtering is to be used.

ST0002_01_US

ST0002_01_US

Figure 4. SX1230 MCU Mode Application Circuit

The SX1230 is an integrated ISM band transmitter and features a fully integrated frequency synthesizer, modulator and power amplifier. This section describes the operation of the SX1230 and the functionality of these blocks.

5.1. Main Parameters

5.1.1. Center Frequency

The carrier output center frequency, f_{RF} of the SX1230 is programmable via the SPI interface. It is determined by the following equation:

$$
f_{RF} = \frac{\text{freq_rf}(23:0) \cdot f_{XOSC}}{2^{19}}
$$

where freq rf(23:0) is the decimal value of the 24 bit number stored in configuration registers FrfMsb, FrfMid and FrfLsb and f_{XOSC} is the frequency of the crystal oscillator. If the optimal value of 32 MHz is selected for the crystal oscillator, then this results in a programmable frequency resolution of 61.035 Hz.

Note that RF output frequencies are only valid in the bands 290-340 MHz, 431-510 MHz and 862-1020 MHz. Note also, that for ease of use, the band selection process is performed automatically.

5.1.2. Frequency Deviation

The frequency deviation of the SX1230 in FSK mode is given by the following equation:

$$
\Delta f = \frac{f_{XOSC} \cdot \text{df_coeff}(13:0)}{2^{19}}
$$

where df_coeff is the decimal value of the 14 bit contents of the FdevLsb and FdevMsb configuration registers.

5.1.3. Bit Rate

The bit rate (or, depending upon coding, the chip rate) of the SX1230 is given by the following equation:

$$
R_B = \frac{f_{XOSC}}{\text{br_ratio}(15:0)}
$$

where f_{XOSC} is the crystal oscillator frequency, br_ratio is the decimal value of the 16 bit contents of registers BrMsb and BrLsb. Note that for OOK modulation the maximum bit rate is 32.7 kbps which corresponds to a br_ratio(15:0) of 979. The table below gives examples of some of the standard data rates accessible with SX1230.

5. Operation of the SX1230

SX1230

ADVANCED COMMUNICATIONS & SENSING PRELIMINARY DATASHEET

Table 7 Example Standard Bitrates and their Corresponding Register Settings.

5.2. Synthesizer

The frequency synthesizer of the SX1230 is a fully integrated fractional-N third-order sigma-delta phase-locked loop and VCO. Also incorporated are fully integrated third-order and low pass filters which determine the loop bandwidth. All of these features are fully automated and derived from the user bitrate and frequency deviation settings, as described in Sections [5.1.1](#page-11-2) to [5.1.3](#page-11-4).

To ensure the frequency accuracy of the PLL output it is necessary to perform calibration. The calibration process is performed automatically upon power up of the SX1230. However, the calibration feature is also accessible to the user via the SPI configuration register, PllStat (address 0x0A). The calibration is performed by setting bit 2 (pll_cal) high. This ensures that the frequency output accuracy is limited only by the frequency error of the crystal oscillator, the calibration procedure lasts 500 µs, during which time pll_cal_done (bit 4 of address 0x0A) is set low. Once complete pll_cal_done is set high and confirmation of a successful calibration can be obtained by reading pll_cal_ok.

pa_ramp_rising_time(6:5)

to deliver the full 17 dBm of output power.

A simplified schematic of the dual power amplifiers of the SX1230 is shown in [Figure](#page-13-1) 5. PA 1 comprises a pair of amplifiers: One dedicated for low power use, LPA, for programmed powers from -18 to -3 dBm: The second for high power use, HPA, for programmed powers from -2 to 13 dBm. PA 2 is a single high power amplifier and may be used in conjunction with PA 1

Figure 5. Simplified Schematic of the SX1230 Power Amplifier

The mode of operation of the PA's is determined by the register setting pa_select(1:0) which is configured as shown in Table 8, below. The output power of the PA is determined by the value of the register pow_val(4:0), with a single PA enabled the output power is set by:

$$
Pout = -18 \text{ dBm} + pow_val(4:0)
$$

The default setting for this register is 13 dBm. The expressions for the output power with other combinations of power amplifier enabled is shown in [Table 8.](#page-13-2) Note also that the power amplifier current limiter, over current protection (OCP), feature of SX1230 can also limit the output power. To ensure correct operation at 17 dBm ensure that trim_ocp(3:0) is set to 105 mA ('1100').

Table 8 Power Amplifier Mode Selection Truth Table

The ramp and power control features of the PA, determine the regulator output voltage which is used to power the amplifiers, this must be done through an external RF choke.

6. Digital Control and Interface

The SX1230 has several operating modes, configuration parameters and internal status indicators which are stored in internal registers. In MCU mode, all these registers can be accessed by the external microcontroller via the SPI interface. In stand alone mode, both the configuration information and the data to be transmitted are stored in an external E^2 PROM. The way that both the configuration and payload information is stored in the E^2 PROM must match the way the configuration is defined in the internal registers. For a full description see Section [6.1.2.](#page-14-3)

6.1. Stand Alone Mode

6.1.1. State Machine Description

The stand alone mode is activated when the pin E2_Mode is tied to VDD. The SPI interface is then configured in master mode. The internal state machine of the SX1230 then carries out the following operations:

1) Immediately after power-up, the SPI interface reads the main configuration section in the E^2 PROM and then goes into the 'sleep' operating mode (i.e. all blocks off).

2) Whilst in 'sleep' operating mode, when an edge is detected on any of the push-buttons PB[3:0], the chip wakes-up and starts the RC oscillator (typical startup time ~100 µs).

3) The RC oscillator clocks a debouncer which gives the button actual value after a delay. The frame section corresponding to the button value (1 to 15) is read from the E^2 PROM. At this point additional, button specific, configuration information may be loaded. Otherwise the configuration settings of 1) are used. Using the appropriate configuration, the payload corresponding to the detected button press is transmitted. The payload transmission may be repeated up to 254 times.

4) When the frame has been transmitted, the pad PLL_LOCK goes low and the chip goes into SLEEP mode.

6.1.2. Memory Organization of the E2PROM

The memory map for stand alone mode is shown in [Figure 6.](#page-15-0) The configuration information occupies the first 77 bytes, the format of the configuration is {ADDR; VALUE} - therefore allowing up to 38 registers to be defined. Each push button configuration is mapped directly to a location in the E^2 PROM determined by the mappings given in [Table 9](#page-15-1) and the variable section_size(5:0). The purpose of this variable push button specific section size is to allow the optimum use of different sizes of external memory. Note that the maximum frame length is 64 bytes - this equates to a maximum E^2 PROM size of 8 kbit. The influence of the section_size variable is illustrated in [Figure 6.](#page-15-0)

The mapping of [Table 9](#page-15-1) permits up to 15 frames to be defined. Each section may contain both write registers commands and the payload to be transmitted. Thus allowing the dynamic configuration of settings such as output power and frequency in response to a button push. Each section within the E^2 PROM must conform to the following format: {FIFO_ADDR; REPEAT; LENGTH; VALUE_1; VALUE_2;...;VALUE_N}. Where VALUE_1... N is the user defined payload, REPEAT is the number of times the frame is to be transmitted, LENGTH defines the number of bytes in the message and FIFO_ADDR = 0x95.

The push-buttons may need to be debounced before being read. The debouncer time constant is programmed by the debounce time(2:0) register which allows a range of debounce timer values to be accessed from 470 μ s to 480 ms. An

SX1230

SX1230

Integrated Transmitter IC

ADVANCED COMMUNICATIONS & SENSING PRELIMINARY DATASHEET

option for no debouncing is also available. Note that time constants are process and temperature dependent and may vary by $+/- 15%$.

Figure 6. Memory Mapping in Stand Alone Mode

The table below gives the push button mappings for the determination of E^2 PROM memory locations. Note that the combinations PB[3:0] = '0001', '0010', '0100' and '1000' are mapped to the four lowest locations in memory. This mapping allows the use of a simple four button interface with the minimum memory size.

Table 9 Push Button Combination to E2PROM Memory Location Mapping

PB[3:0]	PB_MAPPING(3:0)	PB[3:0]	PB_MAPPING(3:0)	
0000	None (no active push-button)	1000	3	
0001	0	1001	7	
0010	1	1010	8	
0011	4	1011	11	
0100	$\overline{2}$	1100	9	
0101	5	1101	12	
0110	6	1110	13	
0111	10	1111	14 / Low Battery	

The commands in the E^2 PROM are written as instructions thus bit 7 is set high - equivalent to adding 0x80 to the register address to be programmed. As was shown in [Figure 6,](#page-15-0) the first 77 bytes are used for configuration. Note that registers only require programming if they hold a value other than the default value (see table 11 for default register settings).

ADVANCED COMMUNICATIONS & SENSING PRELIMINARY DATASHEET

The following table gives an example snippet of E^2 PROM contents, here for each location in E^2 PROM memory the first 13 bytes of the available 77 (0x4C) bytes are occupied with configuration. The remaining bytes are left in their default 0xFF setting. The first push-button memory location is at 0x4D. Here we see that the periodic mode timer (see following section for a full description) is configured and a 10 byte payload follows. Subsequent push buttons are configured at the locations determined by the section size, see [Figure 6.](#page-15-0)

Table 10 Example External SPI E2PROM Contents for SX1230 Configuration

Subsequent button push button configuration and payload could follow at address 0x5C, respecting the E²PROM section size constraint. Note that if register 0x00 is configured, care should be taken to enable transmit mode - mode(2:0) to ensure reliable transition to transmit mode.

6.1.3. Periodic mode

Periodic mode is a sub-mode of stand alone mode wherein the SX1230 will periodically sense the push button inputs for activity. If a push button input is high then the payload according to that input is transmitted. The wake-up interval, *Twakeup*, is defined by periodic_n(3:0) and periodic_d(3:0) values.

$$
T_{\text{wakeup}} = 2 \cdot T_{RC} \cdot (\text{periodic_n}(3:0) + 1) \cdot 2^{\text{periodic_d}(3:0) + 9}
$$

SX1230

ADVANCED COMMUNICATIONS & SENSING PRELIMINARY DATASHEET

where T_{RC} is the RC oscillator period, periodic n is programmable between 0 and 15 and periodic d may take values between 0 and 10. The maximum period is hence approximately 125 s when the frequency of the RC oscillator is 67 kHz. Push button mode is enabled when the value of D is non-zero and, when activated, all stand alone mode functionality is available. It is important to note that if there is no push button pressed, then no message will be transmitted.

6.1.4. Low Battery Indicator: Stand Alone Mode

The low battery indicator may be used in stand alone mode to detect the battery voltage and send a low battery message to the receiver. It is enabled by setting the eol_frame_mode bit 'high' (register 0x12). The low battery state is determined by comparing the supply voltage with a 1.695 V to 2.185 V programmable threshold (threshold trim eol(2:0), address 0x12). Following detection, the following actions are performed depending upon the exact mode of operation:

Normal Operation (Non-Periodic): The battery end-of-life condition is checked during the normal frame. If it is true, then a single extra frame #14 (see [Table 9](#page-15-1)) is automatically sent after the normal frame.

Stand-Alone Periodic Mode Operation: The battery end-of-life condition is checked during the normal frame. If it is true, then the next frame, sent at the next timer tick is frame #14 (see [Table 9](#page-15-1)), the frame is sent only once.

6.1.5. Low Battery Indicator: MCU Mode

In MCU mode the low battery status indicator may be accessed and configured via the SPI register EolCtrl. Alternatively, the active high low battery indication is mapped to the PB0 pin allowing the independent generation of hardware interrupts.

6.2. MCU Mode

6.2.1. SPI Operation

The first byte in any data transfer over the SPI is the address read/write byte. It comprises:

- 1. W/RB bit, which is 1 for write access and 0 for read access
- 2. 7 bits of address, MSB first.

A transfer always starts by the NSS (not slave select) signal going low whilst SCK is high. MOSI (master out - slave in) is generated by the master on the next falling edge of SCK and is sampled by the slave on the next rising edge of SCK. MISO is generated by the slave on the falling edge of SCK and is high impedance when NSS is high. By convention, all bytes are sent MSB first.

MCU mode is activated when pad E2 Mode is tied to GND (ground). In this mode the SX1230 is configured as SPI slave and its internal configuration registers can be written following the format shown in [Figure 7.](#page-18-0)

An 'address write' byte followed by a data byte is sent for a write access. Where multiple sequential registers are to be written, the NSS input may be kept low after this first address byte plus data byte have been sent. In this state sequential data bytes may be written, the address is automatically incremented after the reception of each additional data byte. This allows the sequential data bytes to be written without the need for an address byte. NSS must then be set 'high' after the last byte transfer.

SX1230

Integrated Transmitter IC

ADVANCED COMMUNICATIONS & SENSING PRELIMINARY DATASHEET

Figure 7. Register Write Access

Figure 8. Register Read Access

Similarly the configuration registers of the SX1230 can be read by issuing an 'address read byte' (see [Figure 8](#page-18-1)) the corresponding register contents are then transferred over the MISO line. As above, the contents of each subsequent register can be transferred by holding the NSS input low.

A summary of all of the registers of the SX1230 are given in [Table 11,](#page-20-1) this is followed by detailed descriptions of each of the registers in [Table 12](#page-21-0).

6.2.2. Data and Data Clock Usage

In MCU mode the data to be transmitted is applied exclusively via the DATA input. The DATA input is sampled at the crystal frequency, *fxosc.* Where the MCU mediates the data rate and no gaussian or bit filtering is required, then the use of the data clock signal is optional. However, where filtering is to be used, or the specified data rate accuracy is to be achieved then the rising edge of the data clock, DCLK, signal must be used to clock the data into the SX1230 DATA input.

7. SX1230 Application Circuits

7.1. SX1230 E2PROM Mode Application Circuit

[Figure 10](#page-26-2) shows the standard E^2 PROM connection for stand alone mode operation of the SX1230. With a preconfigured E^2 PROM (see Section [6.1](#page-14-1) for a full description of operation) upon connection of the battery to this circuit the SX1230 reads the configuration section of the E^2 PROM then sends itself into sleep mode. Both devices remain in sleep mode until a keypress is detected.

Once a key is pressed the SX1230 wakes up and starts the RC oscillator. After a user defined wait period, to allow debouncing and determined by debounce_time(2:0), the frame corresponding to the button press is read and transmitted. Once the transmission is complete, both the SX1230 and the E^2 PROM return to their sleep mode configuration. For the corresponding receiver application circuit please see [Figure 12.](#page-28-2)

Figure 10. The SX1230 Stand-Alone Mode Application Circuit

ADVANCED COMMUNICATIONS & SENSING PRELIMINARY DATASHEET

7.2. SX1230 MCU Mode Application Circuit

Figure 11. Interfacing the SX1230 to an MCU

[Figure 11](#page-27-2) shows conventional MCU mode configuration of the SX1230 - here the interface to the SX1230 is performed using 5 MCU pins. In this mode the MCU acts as SPI master exercising total control of the SX1230. For further economy the MCU clock may be driven using the clock output of the SX1230 which can provide several fractions of the crystal oscillator frequency from the fundamental to 1/32 depending upon the setting of clkout select(2:0).

7.3. Complete RKE Application Circuit

Compatible Semtech receivers for RKE applications are the SX1213 (315 and 434 MHz bands) and the SX1210 (868 and 915 MHz ISM bands), the application circuit for which is shown in the proceeding figure. With both transmitter and receiver configured for wide-band operation, (frequency deviation of 150 kHz), and both devices employing crystals with 50ppm frequency stability, the worst case frequency error between Tx and Rx is 31.5 kHz.

ADVANCED COMMUNICATIONS & SENSING PRELIMINARY DATASHEET

Figure 12. SX1213 RKE Demonstration Receiver

7.4. Wake-up Times

When switching between modes, an optimized sequence of events is automatically performed by SX1230. For example, in response to the command to enter transmit mode whilst in sleep mode, each intermediate mode is engaged - ensuring crystal oscillator start-up and PLL lock before transition to transmit mode. External indication of PLL lock is given by the PLL lock pin (MCU mode only). The PLL lock pin output is only valid whist no data is applied to the DATA pin. The transition from frequency synthesizer mode to transmit is well defined and a function of bit rate and transmit ramp time, given in FSK mode by:

$$
TS(\mu s) = 5 + 1.25 \cdot pa_ramp_rising_time(3:0) + \frac{1}{2 \cdot R_B}
$$

where pa_ramp_rising_time(3:0) is the user defined contents of PaFskRamp and R_B is the bit rate. For OOK mode the time is given by:

$$
TS_{\perp}TS(\mu s) = 5 + \frac{1}{2 \cdot R_B}
$$

A flow chart showing the automatic, optimised start-up procedure, initiated with a single SPI command is shown in [Figure 14.](#page-29-0) Note that after the PLL lock indicator is set then the transmitter requires TS_TR to set-up before transmission may begin.

7.5. Reset Pin Timing

Manual reset of the SX1230 is possible by asserting a logical high to the reset pin. The timing for this operation is shown in the following figure. During the reset operation the SX1230 current consumption may rise to 1 mA. Following the reset operation the user must wait 5 ms before performing any other operation.

ADVANCED COMMUNICATIONS & SENSING PRELIMINARY DATASHEET

7.6. Operation with 17 dBm Output Power

With both power amplifiers enabled the SX1230 can generate a 17 dBm (50 mW) output. Starting with the default power amplifier configuration, the register changes necessary to avail of the full output power are:

- The over current protection limiter (OCP) through which the PA is biased must be increased to 105 mA.
- ◆ Both PA1 and PA 2 must be enabled.
- A programmed power output (pow_val) must be set to 13 dBm.

The ideal matching network for full regulatory compliance with FCC Part 15 for 915 MHz operation is shown in [Figure 15](#page-30-1) where, in addition to matching, is an additional discrete notch filter for harmonic rejection.

Figure 15. Single 17 dBm Matching Circuit for both 902-928 MHz (FCC) and 868 MHz (ETSI) Compliance

Figures 9 and 10 show the circuit diagrams of the 434 MHz ETSI and 315 MHz FCC compliant matching schemes. Although the full power may not necessarily be availed of in these bands, 17 dBm operation can permit the use of lower gain, electrically small antennas.

SX1230

Figure 17. Output Matching for 17 dBm Output Power in the 315 MHz Band

The following table shows typical measured power values for the harmonics of the fundamental using each of the three matching schemes above. Note that the harmonic levels are in full compliance with the regulations appropriate to each band with substantial margin.

7.7. Matching for 13 dBm Output Power and Below

For operation at or below 13 dBm of output power, the matching configuration of the following figures is recommended for use in the 915 MHz, 868 MHz and 434/351 MHz bands respecitvely. Whilst the 17 dBm matching of the preceeding section can be used, the adoption of the following matching configurations will guarantee that the current consumption in transmit mode is optimized.

7.8. PCB Layout Considerations

Thanks to its fully integrated architecture PCB layout with the SX1230 can be straight forward. It is nonetheless a high performance RFIC therefore, to attain the best RF performance, certain design rules should be adhered to:

- When designing the a PCB layout for the SX1230 the use of at least two metallized layers is advised, one side forming the populated (component) layer, the second forming a continuous ground plane. Ideally this ground plane should be unbroken and be situated beneath the SX1230 circuit and RF signal path. Adopting this layout strategy minimizes the
potential for spurious emission from, and coupling to, the SX1230.
- Decoupling components should be located as close as possible to the SX1230, ideally each with its own via connection direct to the ground plane.

ADVANCED COMMUNICATIONS & SENSING PRELIMINARY DATASHEET

SX1230

- The crystal oscillator circuit is differential, so benefits from both symmetrical layout and proximity to the SX1230.
- The RF signal path should be kept as straight as possible, ideally duplicating the SX1230 reference design (SM1230).

For a more detailed treatment of the PCB layout for semtech devices please see application note AN1200.04 "RF design guidelines: PCB layout and circuit optimization".

8. Reference Design

Figure 21. SX1230 Reference Design

The SX1230 reference design in shown above with connections for MCU mode operation. The values of all band independent components are shown, for the appropriate RF matching please see Section [7.6](#page-30-0). The corresponding 2-layer PCB layout is shown in [Figure 22](#page-33-1). The example design size for the radio portion of the design (not including push button or stand alone mode functionality) is encompassed by the green box whose largest dimensions are 19 x 10 mm.

11. Recommended PCB Land Pattern

NOTES:

1. CONTROLLING DIMENSIONS ARE IN MILLIMETERS (ANGLES IN DEGREES).

- 2 THIS LAND PATTERN IS FOR REFERENCE PURPOSES ONLY. CONSULT YOUR MANUFACTURING GROUP TO ENSURE YOUR COMPANY'S MANUFACTURING GUIDELINES ARE MET.
- 3. THERMAL VIAS IN THE LAND PATTERN OF THE EXPOSED PAD SHALL BE CONNECTED TO A SYSTEM GROUND PLANE. FAILURE TO DO SO MAY COMPROMISE THE THERMAL AND/OR FUNCTIONAL PERFORMANCE OF THE DEVICE.

ADVANCED COMMUNICATIONS & SENSING PRELIMINARY DATASHEET

12. Soldering Profile

The soldering reflow profile for the SX1230 is described in the standard IPC/JEDEC J-STD-020C, max soldering temperature is 260° C.

Note 1: All temperatures refer to topside of the package, measured on the package body surface.
